

**LACAJAAMBAR**

Beekeeping, biodiversity and soulful educational storytelling.

Narrative ebook · ready to publish

Hachi and the secret language of flowers

A clear, gentle guide to honey bee pollination, the relationship between animal and plant, and the interspecies collaboration that helps sustain life.

Core idea: pollination is not just a botanical process. It is a story of cooperation between different species. Hachi tells it from within, with a warm voice and an ecological point of view.

An ebook designed to move a little, explain well, and leave a more vivid image of the relationship between bee, flower and landscape.

OPENING

Hello. I'm Hachi. I'm small, light, and it may seem as if I only fly from flower to flower because I like nectar. But every journey I make is part of something much bigger.

I need flowers. Flowers need me. And in that meeting, the landscape stays alive.

Contents

1. Hachi leaves the hive
2. A flower is not just decoration
3. What pollination is, told by Hachi
4. A relationship between different species
5. From nectar to fruit
6. I am not alone
7. What threatens this collaboration
8. How to help without getting in the way
9. What Hachi wants you to remember
10. Closing

Life is not sustained by competition alone. It is also sustained by adjustment, exchange and collaboration between different species.

1. Hachi leaves the hive

I do not fly out on a whim. I leave because the colony needs resources and because outside there is a world full of signals. Light, temperature, scents, humidity, season, memory of the land. Everything matters.

When a honey bee leaves to forage, she does not do it like someone wandering without direction. She goes out to read the landscape. She looks for nectar for energy. She looks for pollen to feed the brood. She looks for continuity. She looks for blooms worth the journey.

Each trip seems small. But thousands of trips build an immense network between hive, plant and territory.

2. A flower is not just decoration

For me, a flower is more than something beautiful. It is an invitation, a strategy and a meeting point. It has shape, colour, texture, scent and structure. Many flowers have evolved to attract certain visitors and make it easier for pollen to travel.

I do not go to a flower to do it a sentimental favour. I go because I need something. The flower does not offer nectar out of romantic generosity either. It offers it because it needs someone to carry its pollen. It is not charity. It is biological cooperation.

3. What pollination is, told by Hachi

When I enter a flower, some pollen sticks to my body. Later, when I visit another compatible flower, part of that pollen may reach the right place for the plant to complete its reproduction. That is pollination.

I do not create fruit by magic. I do not produce seeds by intention. But I help the plant continue its cycle. While I gather food, the plant increases its chances of fertilisation.

4. A relationship between different species

I am an animal. The flower is a plant. We do not think alike. We do not live alike. And yet, we cooperate.

The honey bee does not exist apart from the land. The flower does not exist apart from its visitors. The landscape does not exist apart from those links. Together, they make possible something that would not happen in quite the same way if they were separate.

5. From nectar to fruit

I do not create the flower, the tree or the orchard. But my passage can improve the outcome of many plant processes. When pollination works well, some fruits may form better, viable seeds may be produced and plant diversity may be better sustained.

This has ecological consequences, and agricultural ones as well. But before it reaches the plate, pollination is already helping support landscapes, food for wildlife, shelter and biological continuity.

6. I am not alone

Although I am telling this story in the first person today, pollination does not depend on me alone. There are also bumblebees, solitary bees, butterflies, hoverflies and other insects that take part in these networks.

The honey bee matters, yes. But it is not wise to make her the only protagonist of biodiversity. If you truly want to care for pollinators, it is not enough to admire a hive. You also need to think about habitats, blooms, shelter and seasonal continuity.

7. What threatens this collaboration

Some delicate relationships seem eternal, but they are not. When landscapes become too simplified, when wild blooms disappear or when treatments are used carelessly, many of these alliances begin to weaken.

SMALL LOSSES THAT MATTER

- fewer useful flowers
- less shelter
- less diversity
- less water
- more chemical pressure
- more breaks between seasons and resources

8. How to help without getting in the way

If you want to help, you do not need to become a beekeeper tomorrow. You can begin with simple decisions:

- plant useful species for pollinators

- choose blooms spread across the seasons
- keep corners that are more alive and less sterile
- avoid unnecessary treatments
- respect spontaneous flora when it is not a real problem
- encourage landscapes that are less rigid and more diverse

Helping does not always mean adding more. Sometimes it means reducing pressure. Sometimes it means observing better.

9. What Hachi wants you to remember

Do not look at me only as a pretty insect or only as a honey producer. Look at me as part of a biological conversation between different species.

Pollination is about help, yes, but not naive help. It is about real collaboration. Interdependence. The way life learns to sustain itself through others.

10. Closing

I am Hachi. I fly from flower to flower. I look for food for my colony. I carry pollen without turning it into a spectacle. And in that small, repeated and quiet work, I collaborate with plants that are also trying to keep moving through the world.

If you understand that relationship, perhaps you will begin to look at the landscape differently. Not as a collection of separate things, but as a network of collaborations between species.

BONUS 1 · 20 POLLINATOR-FRIENDLY PLANTS

rosemary, thyme, lavender, sage, spike lavender, borage, phacelia, calendula, fennel, clover, broom, heather, blackberry bramble, almond tree, apple tree, local aromatic flora when appropriate, Spanish lavender, savory, marjoram and mallow.

BONUS 2 · KEY IDEAS TO SHARE

- pollination is a relationship between species, not an isolated gesture
- the honey bee looks for food and, in doing so, helps plant reproduction
- a healthy landscape needs floral continuity, shelter and diversity
- caring for pollinators means caring for living relationships

BONUS 3 · SIMPLE ACTIONS

- plant useful diversity, not only decoration
- avoid unnecessary treatments
- keep corners with life in them
- prioritise species adapted to the local climate
- observe the landscape as a network, not as separate pieces

Educational and informative material. If you need to make technical decisions about beekeeping, farming or plant health, it is important to contrast this information with local context and professional judgement.
